Abstract

This database is a joint effort between the National Bureau of Economic Research (NBER) and U.S. Census Bureau's Center for Economic Studies (CES), containing annual industry-level data from 1958-2009 on output, employment, payroll and other input costs, investment, capital stocks, TFP, and various industry-specific price indexes. Because of the change from SIC to NAICS industry definitions in 1997, the database is provided in two versions: one with 459 four-digit 1987 SIC industries and the other with 473 six-digit 1997 NAICS industries.

For questions regarding this data collection, please contact: Please forward all inquiries to: Wayne Gray, Clark University and NBER, wgray@clarku.edu or Randy Becker, Center for Economic Studies, U.S. Census Bureau, randy.a.becker@census.gov

Additional Information

Methodology

The NBER-CES Manufacturing Industry Database contains annual data from the United States manufacturing sector for the period from 1958 to 2009. The data used for the development of the database come from various sources, but chiefly from four government agencies: the Bureau of the Census, the Bureau of Economic Analysis, the Bureau of Labor Statistics, and the Federal Reserve Board. The goal is to provide a long time-series of data for a large number of industries, adjusting for changes in industry definitions, and creating price deflators, capital stocks, and productivity estimates. This paper describes issues related to the most recent update of the database (1997 to 2009). For a more detailed discussion of an older version of the data see Bartelsman and Gray (1996). The key feature (and complication) of recent updates is the adjustment to the NAICS industry definitions. It is published in two versions: one based on the 1987 Standard Industrial Classification (SIC), containing 459 industries, and the other based on the 1997 North American Industrial Classification System (NAICS), containing 473 industries. The boundaries of the manufacturing sector shifted between SIC and NAICS, with some SIC industries leaving manufacturing and other NAICS industries entering manufacturing. The exiting SIC industries don't have data after 1996, and the entering NAICS industries don't have data before 1997. To enable the calculation of price deflators in each version, the benchmark year for deflators in the NAICS version is 1997, while the SIC version continues to use 1987 as a benchmark. This version of the database recalculates all the data post-1996, and earlier updates of the database (1958-2002 and 1958-2005) are superseded and should not be used. For more information, see methodology in <http://www.nber.org/nberces/t0205.pdf> , technical

notes in http://www.nber.org/nberces/nberces5809/nberces_5809_technical_notes.pdf , information on Concordances (1987 SIC - 1997 NAICS in Stata , SAS , Excel , CSV , PDF , 1972 SIC - 1987 SIC in Stata , SAS , Excel , CSV ,).

Variable Name

vship

Label

Total value of shipments in \$1m

Concept

Type

numeric

Files

F1csv F1dta F1sas F1xls

Full Description

Value of industry shipments (millions of dollars). These are based on net selling values, f.o.b. plant, after discounts and allowances. This includes receipts for contract work and miscellaneous services provided by the plant to others. VSHIP is not adjusted for inventory changes, and can include large amounts of duplication across industries or even across plants in the same industry (especially machinery and transportation industries that often include production of parts as well as final products).

Summary Statistics

Variable Name	matcost
Label	Total cost of materials in \$1m
Concept	
Type	numeric
Files	F1csv F1dta F1sas F1xls

Full Description

Cost of materials (millions of dollars). This includes the total delivered cost of raw materials, parts, and supplies put into production or used for repair and maintenance, along with purchased electric energy and fuels consumed for heat and power, and contract work done by others for the plant. This excludes the costs of services used, overhead costs, or expenditures related to plant expansion. Because MATCOST includes energy spending, to calculate spending on non-energy materials one must use (MATCOST-ENERGY).

Variable Name

invest

Label

Total capital expenditure in \$1m

Concept

Type

numeric

Files

F1csv F1dta F1sas F1xls

Full Description

Total capital spending (millions of dollars). This variable underwent a substantial change in definition. The ASM reported new capital expenditures before 1997 (with used capital expenditures in an additional table), but switched to reporting the sum of new and used expenditures in 1997, with no separate breakout of new and used expenditures (even in Census years). In order to maintain consistency with the earlier data, we adjusted the post-1996 data to reflect new expenditures. The data on new and used expenditures from 1987, 1992, and 1996 were combined to derive a fraction new ($\text{new}/(\text{new}+\text{used})$) for each industry, which was then used to adjust the post-1996 capital expenditure numbers to reflect only new expenditures.

Summary Statistics

Variable Name	pimat
Label	Deflator for MATCOST 1987=1.000
Concept	
Type	numeric
Files	F1csv F1dta F1sas F1xls

Full Description

The materials cost deflators are calculated using data from the use-make (input-output) tables and the GDP-by-Industry data of the Bureau of Economic Analysis (BEA). The raw data are available at the BEA website (<http://www.bea.gov>) under the Industry tab. The use-make tables disaggregate each industry's total materials cost into the amount spent on each specific material. The share of each material in the industry's total materials cost is then used to weight each material's price index, resulting in a weighted-average price index for the industry's total materials cost. The benchmark versions of the use-make tables, which are generated every 5 years, are used. A moving average of the weights from the two surrounding benchmark years is used to interpolate the weights for the use-make tables in the intervening years. Inputs coming from manufacturing industries use the price index in the database for that industry's shipments. Inputs coming from other (non-manufacturing) sectors use that sector's price index for gross output.

The main difficulty with implementing the above procedure is the lack of a clear one-to-one correspondence between the industry codes used in the use-make tables and those used in the ASM/CMF data. The use-make tables contain many fewer industries than the NAICS industries. BEA does provide concordance tables, which are supplemented with some manual matching based on industry definitions. We assume that all NAICS industries which map into the same use-make industry have the same structure of inputs.

To match MATCOST, this is a deflator for all materials, including energy. If you need a separate 'non-energy materials' deflator, you can construct an implicit one, based on $(\text{MATCOST}/\text{PIMAT}) - (\text{ENERGY}/\text{PIEN})$.

Variable Name	piinv
Label	Deflator for INVEST 1987=1.000
Concept	
Type	numeric
Files	F1csv F1dta F1sas F1xls

Full Description

Price deflator for new investment (equals 1 in 1987). This combines separate deflators for structures and equipment, based on the distribution of each type of asset in the industry. Note that this is a deflator for new investment flows, not for the existing capital stock. The ASM provides annual data for gross nominal capital expenditures on equipment and structures. However, it lacks information on depreciation rates and investment deflators, which are necessary in order to construct the real capital stocks in the database.

Depreciation rates are derived from Federal Reserve Board data (FRB). Depreciation rates are calculated for each industry, backing them out of a standard perpetual inventory equation: $K_t = (1-d_{t-1})K_{t-1} + I_t$, where d is the rate of depreciation, K is the real capital stock in years t and $t-1$, and I is the real capital investment in year t .

To calculate the investment deflator, price indexes for equipment and structures are computed from the ratios of nominal and real investment for the 4-digit NAICS industries in the FRB data. The final deflator values are created as the weighted mean of the two types of capital expenditures. The shares used for the weights are averaged over years t and $t-1$. For detailed information please refer to http://www.nber.org/nberces/nberces5809/nberces_5809_technical_notes.pdf

Variable Name	pien
Label	Deflator for ENERGY 1987=1.000
Concept	
Type	numeric
Files	F1csv F1dta F1sas F1xls

Full Description

Price deflator for energy (equals 1 in 1987). The energy deflator is based on each industry's expenditures on seven types of energy: electricity, residual fuel oil, light oils, liquefied petroleum, coal, coke, and natural gas. Previous updates used information for six types of energy (the distillates category was recently split into light oils and liquefied petroleum).

As with the materials cost deflator, we combine price indices for the different energy types with information on each energy type's share in the industry's total energy expenditures. Data on energy expenditures for six fuels (excluding electricity) come from 2002 Manufacturing Energy Consumption Survey (MECS). The data on energy expenditures for six of the fuels in the current update (excluding electricity) come from the 2002 Manufacturing Energy Consumption Survey (MECS), available at the Bureau of the Census website (<http://www.census.gov>). The ASM data provide information on electricity and non- electricity energy spending, and the MECS data are used to disaggregate each industry's non-electricity spending share into the share of each of the six non-electricity energy types. There are a number of missing values in the MECS data. Extremely small values (less than 0.5), as well as values with high relative standard error (more than 50%) are withheld from the official MECS release by Census. Additionally, some values are withheld to avoid disclosing information for individual establishments in cases where an industry relatively few plants. The extremely small values are replaced by 0.1. Price indexes for each non-electricity energy type are obtained from the Bureau of Labor Statistics database (<http://www.bls.gov>), using the industrial price indexes. The codes of the extracted BLS variables are:

- WPU051 Coal
- WPU052 Coke oven products
- WPU0532 Liquefied petroleum gas
- WPU054321 Industrial electric power
- WPU055321 Industrial natural gas
- WPU0573 Light fuel oils
- WPU0574 Residual fuels

Since the 1996 update, the WPU052 Coke oven products series has been discontinued. Thus, the coke price data used here are extrapolated from coal prices. Electricity prices are calculated from the industry- specific electricity consumption and expenditures data in the ASM tables, where available, and otherwise taken from the national-average values.

Variable Name	dtfp5
Label	5-factor TFP annual growth rate
Concept	
Type	numeric
Files	F1csv F1dta F1sas F1xls

Full Description

There are two versions of TFP in the NBER-CES Manufacturing Database: 4-factor and 5-factor. The 5- factor version separates out energy from non-energy materials; the 4-factor uses a single materials input (which includes energy). The TFP calculation requires definitions of the cost shares, the factors, the factor changes, and the output changes. The five cost shares (α_i) vary by industry by year, defined using the variable names in the dataset:

- (α_1) Non-production workers: $(\text{pay-prodw})/\text{vship}$ [i.e., their pay divided by shipments]
- (α_2) Production workers: $\text{prodw}/\text{vship}$ [i.e., their pay divided by shipments]
- (α_3) Energy: $\text{energy}/\text{vship}$ [i.e., energy expenditure divided by shipments]
- (α_4) Materials: $(\text{matcost-energy})/\text{vship}$ [i.e., non-energy materials divided by shipments]
- (α_5) Capital: $1 - (\text{sum of the above shares})$ [i.e., the residual]

In calculating TFP growth from one year to the next, we use the average of the two years' cost shares: $\bar{\alpha}_{it} = 0.5\alpha_{it} + 0.5\alpha_{it-1}$. The 5 factors (X_i) are defined as follows, using the variable names in the dataset:

- (X_1) Non-production workers: (emp-prode) [i.e., the number of non-production workers]
- (X_2) Production workers: prodh [i.e., production worker hours, not employees]
- (X_3) Energy: $(\text{energy}/\text{pien})$ [i.e., real energy expenditures]
- (X_4) Materials: $((\text{matcost}/\text{pimat}) - (\text{energy}/\text{pien}))$ [i.e., real non-energy materials]
- (X_5) Capital: cap [i.e., total capital stock, already in real terms]

The change in factor usage between one year and the next is defined as the change in natural logs, (for example):

$$\Delta X_{it} = \ln(X_{it}) - \ln(X_{it-1})$$

We also need the change in real output: (Q) Real output: $\text{vship}/\text{piship}$

As with factor usage, we express output change in terms of natural logs, hence: $\Delta Q_t = \ln(Q_t) - \ln(Q_{t-1})$

The change in 5-factor TFP (ΔTFP_5) between this year and last is thus defined as: $\Delta \text{TFP}_5_t = \Delta Q_t - \sum_i (\alpha_i \Delta X_{it})$, $i = 1, \dots, 5$

Given the series of dTFP5 values, one can then "roll up" these changes to form a TFP index (TFP5), by setting the index equal to 1.0 in some initial year `t` and then growing the index forward by the following equation: $TFP5_{t+1} = \exp[\ln(TFP5_t) + (dTFP5_{t+1})]$

The values of 4-factor TFP growth (dTFP4) and the corresponding TFP index (TFP4) are calculated similarly, but using total materials cost spending rather than separating it into energy and non-energy materials.

The change in factor usage between one year and the next is defined as the change in natural logs, (for example):

$$\Delta X_{it} = \ln(X_{it}) - \ln(X_{it-1})$$

We also need the change in real output: (Q) Real output: $\text{vship}/\text{piship}$

As with factor usage, we express output change in terms of natural logs, hence: $\Delta Q_t = \ln(Q_t) - \ln(Q_{t-1})$

The change in 5-factor TFP (ΔTFP_5) between this year and last is thus defined as: $\Delta \text{TFP}_5_t = \Delta Q_t - \sum_i (\alpha_i \Delta X_{it})$, $i = 1, \dots, 5$

Given the series of dTFP5 values, one can then "roll up" these changes to form a TFP index (TFP5), by setting the index equal to 1.0 in some initial year `t` and then growing the index forward by the following equation: $TFP5_{t+1} = \exp[\ln(TFP5_t) + (dTFP5_{t+1})]$

The values of 4-factor TFP growth (dTFP4) and the corresponding TFP index (TFP4) are calculated similarly, but using total materials cost spending rather than separating it into energy and non-energy materials.

Full Description

There are two versions of TFP in the NBER-CES Manufacturing Database: 4-factor and 5-factor. The 5-factor version separates out energy from non-energy materials; the 4-factor uses a single materials input (which includes energy). The TFP calculation requires definitions of the cost shares, the factors, the factor changes, and the output changes. The five cost shares (α_i) vary by industry by year, defined using the variable names in the dataset:

- (α_1) Non-production workers: $(\text{pay-prodw})/\text{vship}$ [i.e., their pay divided by shipments]
- (α_2) Production workers: $\text{prodw}/\text{vship}$ [i.e., their pay divided by shipments]
- (α_3) Energy: $\text{energy}/\text{vship}$ [i.e., energy expenditure divided by shipments]
- (α_4) Materials: $(\text{matcost-energy})/\text{vship}$ [i.e., non-energy materials divided by shipments]
- (α_5) Capital: $1 - (\text{sum of the above shares})$ [i.e., the residual]

In calculating TFP growth from one year to the next, we use the average of the two years' cost shares: $\bar{\alpha}_{it} = 0.5\alpha_{it} + 0.5\alpha_{it-1}$. The 5 factors (X_i) are defined as follows, using the variable names in the dataset:

- (X_1) Non-production workers: (emp-prode) [i.e., the number of non-production workers]
- (X_2) Production workers: prodh [i.e., production worker hours, not employees]
- (X_3) Energy: $(\text{energy}/\text{pien})$ [i.e., real energy expenditures]
- (X_4) Materials: $((\text{matcost}/\text{pimat}) - (\text{energy}/\text{pien}))$ [i.e., real non-energy materials]
- (X_5) Capital: cap [i.e., total capital stock, already in real terms]

The change in factor usage between one year and the next is defined as the change in natural logs, (for example):

$$\text{d}X_{it} = \ln(X_{it}) - \ln(X_{it-1})$$

We also need the change in real output: (Q) Real output: $\text{vship}/\text{piship}$

As with factor usage, we express output change in terms of natural logs, hence: $\text{d}Q_t = \ln(Q_t) - \ln(Q_{t-1})$

The change in 5-factor TFP (dTFP5) between this year and last is thus defined as: $\text{dTFP5}_t = \text{d}Q_t - \sum_i (\alpha_i \text{d}X_{it})$, $i = 1, \dots, 5$

Given the series of dTFP5 values, one can then "roll up" these changes to form a TFP index (TFP5), by setting the index equal to 1.0 in some initial year `t` and then growing the index forward by the following equation: $TFP5_{t+1} = \exp[\ln(TFP5_t) + (dTFP5_{t+1})]$

The values of 4-factor TFP growth (dTFP4) and the corresponding TFP index (TFP4) are calculated similarly, but using total materials cost spending rather than separating it into energy and non-energy materials.
